## Assignment - II

Ans 1 This concept of cyclomatic complexity involves using cyclomatic number of graph theory which has been defined as cyclomatic complexity, this is nothing but the number of independent paths through a program. McIabs introduced this concept and gave three methods to calculate it:

$$\textcircled{i} \quad V(G) = e - n + 2p$$

where,  $V(G)$  : Cyclomatic complexity

$n$  : Number of nodes

$e$  : Number of edges

$p$  : Number of connected components

\textcircled{ii} Equal to number of regions of program.

$$\textcircled{iii} \quad V(G) = \pi + 1$$

where;  $\pi$  : Number of predicate nodes

But, the predicate node should only have two outgoing nodes (one for true and one for false) otherwise this is not valid.

Example

$$\begin{aligned} \textcircled{i} \quad V(G) &= e - n + 2p \\ &= 7 - 5 + 2(1) \\ &= 4 \end{aligned}$$

\textcircled{ii} These are 4 regions in graph inside and outside.

$$\textcircled{iii} \quad V(G) = \pi + 1$$

$$\begin{aligned} &= 3 + 1 \\ &= 4 \end{aligned}$$

$$\therefore \pi = 3; \text{ i.e. } a, c, d \text{ 3}$$

NOTES

Ans 2

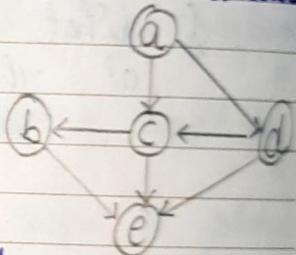

Testing

- Testing is process to find bugs and errors
- It is display of errors.

Debugging

Debugging is the process of correct bugs found in Testing  
It is deductive process.

#### MEETINGS / APPOINTMENTS

- 09     • It is the process to identify the failure of implemented code. It is the process to give the absolution to code failure.
- 10     • It is done by testers. It is either done by developers or programmers.
- 11     • It is not needed to design knowledge in the testing process. It can't be done without proper design knowledge.
- 12     • It can be manual or automated. It can't be automated, it has to be manual.
- 13     • It is based on different testing level i.e. unit testing, integrate types of bugs, system etc.
- 14     • It is a stage of software development life cycle (SDLC). It is not an aspect of software development life cycle, it occurs as a consequence of testing.
- 15     • It is composed of validation and verification of software. It seeks to match symptom to cause, by that it leads to the error correction.
- 16
- 17
- 18
- 19

Ans 3 This technique is a popular technique for small programs and considers the combinations of various input which were not available in techniques like Boundary Value Analysis and equivalence class testing. Such techniques do not allow combinations of inputs and consider all inputs as independent inputs. Two new terms are used here and these are cause & effect, which are nothing but input and output respectively.

Considered Example: Consider example of keeping the record of marital status and number of children of a citizen. The value of marital status

24	25	26	27	28	29	30	

## MEETINGS / APPOINTMENTS

09 must be 'v' or 'm'. The number of children must be digit or null, in case of a citizen. Is unmarried  
 10 If the information entered by the user is correct then an update is made. If the marital status of a user  
 11 is incorrect, then error message is issued. Similarly, if the value of numbers of children is incorrect, then error message2 is issued.

The causes are:-

C<sub>1</sub>: marital status is 'u'

C<sub>2</sub>: marital status is 'm'

C<sub>3</sub>: number of children is a digit, C<sub>2</sub>

The effects are:-

E: updation made

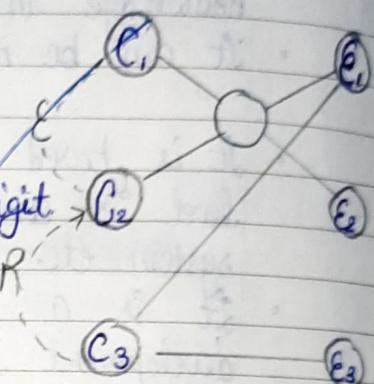

E<sub>1</sub>: error message1 is issued

E<sub>2</sub>: error message2 is issued

The cause and effect graph is shown. These are two constraints exclusive, (between C<sub>1</sub> & C<sub>2</sub>) and requires (between C<sub>3</sub> and C<sub>2</sub>) which are placed at appropriate place in the graph. Cause C<sub>1</sub> & C<sub>2</sub> cannot occur simultaneously and for cause C<sub>3</sub> to be true, C<sub>2</sub> has to be true.

However, there is no mask constraint in this graph.

Identification of all cause & effects

## NOTES

Design the cause-effect graph

Apply constraints (if any)

Design limited entry decision table from graph

Write test cases

MEETINGS / APPOINTMENTS

Ans 4 This is a simple but popular functional testing technique. Here, we concentrate on input values that are on or close to boundary value. Experience has shown that such cases show a higher probability of detecting a fault in the software. Suppose we have a program which takes input from 1-100. So, there is no need to check the program for all the input from 1-100. The number of input selected by this technique is  $(4n+1)$  where 'n' is no. of inputs. We also consider 'single fault' assumption theory of reliability which says that failures are rarely the result of simultaneous occurrence of two(or more) faults. Normally, one fault is responsible for one failure. With this theory in mind, we select one input value on boundary (minimum), just above boundary (maximum), nominal(average) and other n-1 inputs.

Therefore we select from 1-100:

- Minimum value (1),
- Just above minimum value (2),
- Maximum value (100),
- Just below maximum value (99), and
- Average (50).

Boundary value test for largest among 3 numbers [1-100]

Test Case	x	y	z	Expect Output
1	1	50	50	50
2	2	50	50	50

### Ans 6 @ Black Box

- It is the way of software testing in which internal structure in which the tester has knowledge of the program or code is hid about the internal structure or and nothing is known about it the code or program of software.
- Code implementation isn't needed for it.
- Done by software testers.
- No knowledge of implementation is needed.
- It can be addressed as outer or external software testing.
- It is functional testing.
- This testing can be initiated based on the requirement specification document.

### White Box

- Code implementation is necessary for its.
- Done by software developer.
- Knowledge of implementation is required.
- It is inner or internal software testing.
- It is structural testing.
- This type of testing of software is started after a detail design document.

## MEETINGS / APPOINTMENTS

Ans 7 Program slicing was introduced by made wise where we prepare various subsets (called) (slice) of a program with respect to its variable and their selected locations, in the program. Each variable with one of its location will give us a program slice.

"Program slicing is a technique for restricting the behaviour of a program to some specified subset of interest. A slice  $SC(v, n)$  of program  $P$  on variable  $v$  or set of variables, at statement  $n$  yields the portion of the program that contributed to the value of  $v$  just before statement  $n$  is executed."

Example:-

void main()

{

int a, b, c, d, e

printf("Enter the value of a, b and c \n");

scanf("%d %d %d, &a, &b, &c);

d=a+b

e=b+c

printf("%d, d);

printf("%d, e);

}

$SC(e, 10) = (1, 2, 3, 4, 5, 7, 9, 10)$

$SC(e, 7) = (1, 2, 3, 4, 5, 7, 10)$

NOTES  $SC(d, 10) = (1, 2, 3, 4, 5, 6, 8, 10)$

$SC(d, 6) = (1, 2, 3, 4, 5, 6, 10)$

$SC(a, 5) = (1, 2, 3, 4, 5, 10)$

Ans 8 Decision table are used in many engineering disciplines to represent complex logical relationships. An output may be dependent on many input conditions and

09 The 'do not condition' are represented by the '-' sign.  
 A "do not case" condition has no effect on the output  
 10 If we refers to column one of the decision table  
   where condition C:  $a < b + c$  is false, then other entry  
 11 become "do not case" entries. If C. is false the output  
   will be filled triangle irrespective of my state(true/false).  
 12 These condition become do not case condition and are  
   represented by (-) sign. If we don't do so and repre-  
 13 sented all true and false entries of every condition, the  
   decision table will unnecessarily increase.

14 This is nothing but a representation facility in the  
   decision table to reduce the number of columns and  
 15 avoid redundancy. Ideally each column has one rule and  
   that leads to a test case.

16 The term rule count is used with "do not case" entries  
   in the decision table and has a value 1, if "do not  
 17 case" condition is not there, but doubles for each  
   "do not case" entry.

18 Rule Count = 2 (Number of 'do not case' condition)
